Proposed model structure

#### Motivation

### Advantages

- + easier maintainance of the model code
- faster introduction of scientific novelties that may emerge from COSMO countries and the from the "formerly called" LM-users (urban and climatological features, chemistry) in the mainstream code without affecting the stability for operational NWP
- + native (re)introduction of features, like 2-way nesting, abandoned because of complexity and bugs
- more natural introduction of new features that are required by the changes in the scientific scenario, like new Data Assimilation techniques, (4Dvar or whatever?) etc.

#### Motivation

Structure of a class

### Definition of a class-like module in F90, storage

```
MODULE spacetime_grid_class
USE datetime_class
IMPLICIT NONE
```

```
PRIVATE
PUBLIC spacetime_grid, ini_t, act_t, fin_t
```

```
TYPE(datetime) :: ini_t, act_t, fin_t ! Class static variables
```

```
TYPE spacetime_grid ! Instance variables
    PRIVATE
    TYPE(datetime) :: ini_t, act_t, fin_t
    TYPE(timedelta) :: dt
    INTEGER nx, ny
END TYPE spacetime_grid
```

END MODULE spacetime\_grid\_class

Structure of a class

### Definition of a class-like module in F90, storage

```
PRIVATE
PUBLIC spacetime_grid, ini_t, act_t, fin_t
TYPE(datetime) :: ini_t, act_t, fin_t ! Class static variables
```

- PRIVATE should be the default whenever possible
- class public static storage should be limited to the minimum necessary (truly global variables needed by other classes)

This will avoid having long lists of USE ... ONLY in order to document the external variables and will reduce the cross-dependencies between classes.

Object-oriented-like approach in F90

Proposed model structure

References

Structure of a class

# Definition of a class-like module in F90, storage

```
TYPE spacetime_grid ! Instance variables
    PRIVATE
    TYPE(datetime) :: ini_t, act_t, fin_t
    TYPE(timedelta) :: dt
    INTEGER nx, ny
END TYPE spacetime_grid
```

 the class instance storage should have the PRIVATE attribute when possible, but this is not as strict as the previous guidelines

This will give more freedom to change the internal structure of the class without affecting the procedures that USE it.

Description of the main classes

# Integration tree class

The main class which drives the integration process is called integration\_tree:

- describes a full application of the "model operator" on a single grid
- carries pointers to objects of the same class describing parent grid and child grid(s)
- the "root" of the integration tree could be the driving model data interpolated on the main computational grid (special case of "non prognostic" integration\_tree object)
- the child of the root grid would then be the main "prognostic" grid
- the child(ren) of the main computational grid may represent nested grids and so on

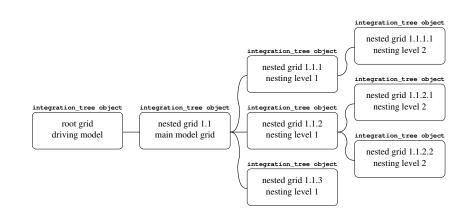

Object-oriented-like approach in F90

Proposed model structure

References

Description of the main classes

### Scheme of the integration\_tree grid hierarchy

Proposed model structure

References

Description of the main classes

### Integration tree class contents

The integration\_tree class contains classes representing all the numerical packages of the model: dynamics, physics (each parameterization should reside in a separate subclass), assimilation, chemistry, etc. + Input/Output

- these classes are assumed independent one of each other, this makes the management of the code easier but may restrict the freedom in developing numerical modules
  - ⇒ two classes (modules) cannot reference each other (circular references forbidden in f90), so if two classes (e.g. convection and turbulence parameterisation) have to share some piece of code or data, this piece should be extracted from the two classes and placed in a separated module USE'd by both.

Object-oriented-like approach in F90

Description of the main classes

### Management of model variables

In order to simplify the management of variables and variable tables, the variables are handled by the model\_variable class (contained in integration\_common class) with the following phases:

Proposed model structure

References

#### Description of the main classes

### Management of model variables

### • model\_variable class reads the variable table from a file

- all the numerical modules, after reading the configuration, make a "reservation" for the variables they need (identifying them by name), by calling a reserve method in model\_variable class, specifying e.g. whether the variable is prognostic, how it is staggered, etc.
- the alloc method of the model\_variable class is called, which does a sanity check and allocates the variables which have been "reserved"
- at the beginning of every time step, the numerical modules call the get method of the model\_variable class in order to get a pointer to the variables/tendencies needed, at the required time levels

Proposed model structure

References

Description of the main classes

### Management of model variables

This way, adding a model variable is just a matter of inserting its description in a configuration file and inserting the proper "reservation" where the variable is needed

 $\Rightarrow$  easier maintenance and more freedom for scientific developers.

Object-oriented-like approach in F90

Proposed model structure

References

Description of the main classes

# Management of model variables

Another feature —planned but only partially implemented— is the possibility to group different variables into a single one with an additional dimension, in order to simplify the treatment of high numbers of microphysical or chemical species, e.g. in the advection

### Benefits from F2003

Procedure pointers to associate each diagnostic variable to the corresponding method for its computation, may simplify the I/O module.

Procedure pointers to associate prognostic variables to the method for computing falling velocity field, may simplify the advection code.

Object-oriented-like approach in F90

Proposed model structure

(日) (日) (日) (日) (日) (日) (日)

References

Description of the main classes

#### Numerical computing classes

They should have the following methods:

- init (constructor) which sets up the storage, reads the configuration and makes the variable "reservation"
- compute performs computation for a single timestep
- other standardized methods could be added for performing additional operations, like compute\_tangent\_linear, compute\_adjoint, checkpoint, restart...

Object-oriented-like approach in F90

Proposed model structure

◆□▶ ◆□▶ ▲□▶ ▲□▶ ▲□ ◆ ○○

References

Description of the main classes

#### Numerical computing classes

- numerical classes are in principle free to allocate their own private arrays or other kind of data
- these data should be placed in the instance storage (the main TYPE definition) if they have to be conserved between calls and have to be unique to each grid
- they can either update the tendencies of the prognostic variables or the variable themselves in a time-splitting manner

(日) (日) (日) (日) (日) (日) (日)

Description of the main classes

#### Numerical computing classes - alternative schemes

If more than one numerical scheme is available for the dynamics or for a physical parameterization, this could be implemented as a driving class with pointers to the specific numerical classes, rather than physical inclusion of them.

Only the pointer to the desired scheme/class will then be ASSOCIATED (). See also the class scheme.

#### Benefits from F2003

"True" classes with type extension, polymorphism and bounded procedures can help in avoiding code repetition and simplifying the management of the alternative numerical schemes.

Object-oriented-like approach in F90

Proposed model structure

References

Description of the main classes

# Numerical computing classes - software interoperability

- if a more traditional programming approach is desired, where, e.g., prognostic variables are to be called u, v, p, etc. and not this%u, this%v, this%p, then the compute method can act as a wrapper to a traditional routine whose parameters are all the needed variables and configuration parameters
- this would allow to call modules written according to the old "Rules for interchange of physical parameterizations" (Kalnay et. al), either including the old code in the module (better) or leaving it as external routines

Restructuring of the namelist input

## Using xml files instead of namelists

- a special tool reads a description of the "namelist", relative to a single module/class, from an xml file and generates a f90 module source that can read the desired xml structure into a proper f90 derived type
  - the description includes variable types, rank, dimensions (fixed or allocatable runtime) and initial default value
- the module/class needing configuration USEs the automatically generated module and CALLs the corresponding reading routines
- if all the configuration for a module/class is contained in a single derived type (without POINTER variables), it is simpler to exchange it in parallel mode (this would be true for a namelist too, but it is uncomfortable to read a derived type in a namelist)
