20<sup>th</sup> COSMO General Meeting- Saint-Petersburg  
September 3, 2018

## Outline

- Motivation for using prognostic aerosols in radiation & microphysics schemes
- The Segal & Khain (2006) scheme
- New cloud number concentration scenarios in COSMO
- The CAMS model
- Test case of April 25-27, 2018
- Impact on precipitation, radiation, T2m, LWC,  $R_{eff}$
- Overall scores
- Concluding remarks and outlook

# Motivation - radiation

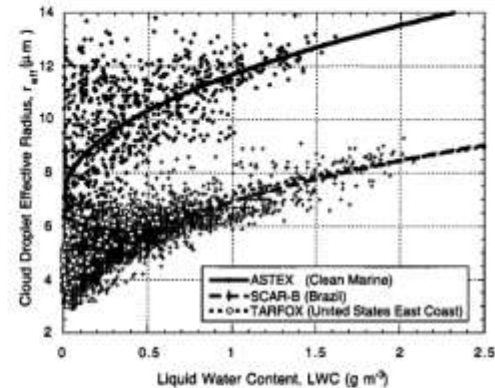

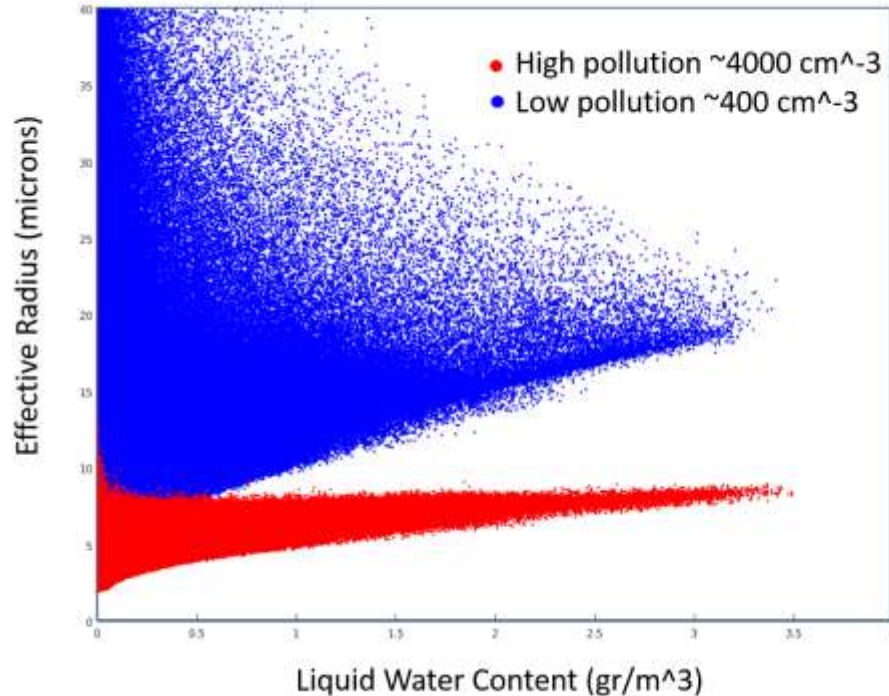

Figure 6. Cloud droplet effective radius ( $r_{eff}$ ) versus liquid water content (LWC) for cumulus clouds in clean marine air over the northeastern Atlantic Ocean (diamonds, Atlantic Stratocumulus Transition Experiment (ASTEX)), in urban-industrial air off on the U.S. east coast (circles, Tropospheric Radiative Forcing Experiment (TARFOX)), and in air masses dominated by smoke from biomass burning (pluses, Brazil).

- Effective radius in SGS clouds in operational mode is fixed number ( $R_{eff} = 5 \mu m$ )
- Effective radius in grid scale clouds in operational mode is based only on LWC
- For iradpar\_cloud=4:

$$R_e = \frac{1}{2} \frac{M_3}{M_2} = c_1 \left( \frac{\rho_x}{n_x} \right)^{c_2}$$

# Motivation - radiation

## Sensitivity of $T_{2M}$ in 7-day experiment to SGS Reff

COSMO-EU / COSMO-DE setup (1-moment microphysics) / **COSMO-DE results:**

# Motivation – clouds formation & precipitation

- Cloud droplets number concentration in the default COSMO 1-mom scheme is fixed to **cloud\_num** ( $500 \text{ cm}^{-3}$ ). In 2-mom schemes it depends on fixed/climatology aerosols number concentrations
- But variations in the densities of aerosols which act as cloud condensation nuclei CCN can have large impact on cloud formation, dynamics and precipitation

Pristine tropical clouds with low CCN concentration can rain out too quickly to mature to long lived clouds

Polluted clouds with very high CCN concentrations may evaporate before rain can occur

# Segal & Khain scheme in COSMO radiation

## Option 1: cloud\_num\_rad

### → icloud\_num\_type\_rad = 1

- $n_C(z)$  has assumed exponentially decreasing vertical profile above  $z_0$ :

$$n_C = n_{C0} \begin{cases} \exp\left(-\frac{z-z_0}{\Delta z_{1/e}}\right) & \text{if } z > z_0 \\ 1 & \text{else} \end{cases} \quad [\text{kg}^{-1}]$$

- **cloud\_num\_rad** is  $n_{C0}$  default  $200 \text{ cm}^{-3}$
- dz\_oe\_cloud\_num =  $\Delta z_{1/e}$  in [m] (half its value every 6000 m).
- zref\_cloud\_num =  $z_0$  in [m] (2000 m)
- $R_{e,C}$  from  $n_C(z)$  and  $q_C(z)$  resp.

$$R_e = c_1 \left( \frac{q_C}{n_C} \right)^{c_2}$$

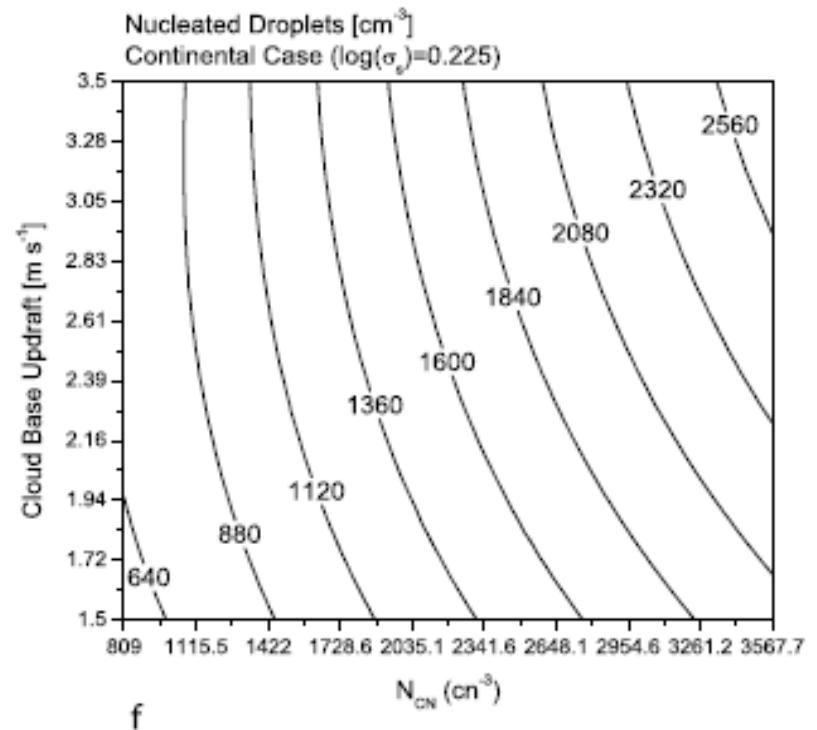

# Segal & Khain scheme in COSMO radiation

## Option 2: Segal & Khain

→ **icloud\_num\_type\_rad = 2 (Tegen) / 4 (CAM5)**

- Cloud nuclei profile  $n_{CN}(z)$  is estimated from Tegen/CAMS aerosols
- Activation of  $n_{CN}$  to  $n_{CCN}$  is estimated from Segal & Khain (2006) parameterization based on the estimated vertical velocity at cloud base
- $n_C$  is assumed equal to  $n_{CCN}$
- 4D look-up table:

$$n_{CCN}^{SK} = f(n_{CN}, \log(\sigma), r_{mod}, W_{CB})$$

Segal & Khain (2006)

# Segal & Khain scheme in COSMO radiation

## Option 2: Segal & Khain activation

- In „active“ clouds ( $w_{nuc} > w_{cb,min}$  and  $q_c > 0$  or  $clc\_con > 0$  over several adjacent height layers), activation is at cloud base and  $n_{CN}$  decreases exponentially above cloud base ( → autoconversion, accretion).
- All other grid points: derive  $n_c$  from lookup table based on local  $n_{CN}$  and  $w_{nuc}$
- Let  $n_{CCN,SK}$  be the lookup table, then:

$$n_c(z) = \begin{cases} n_{CCN,SK}(n_{CN}(z_{cb}), w_{nuc}(z_{cb})) \exp\left(-\frac{z-z_{cb}}{\Delta z_{a,1/e}}\right) & \text{if } w \geq w_{cb,min} \wedge q_c(z) > 0 \wedge z \geq z_{cb} \\ n_{CCN,SK}(n_{CN}(z), \max[w_{nuc}(z), w_{cb,min}]) & \text{else} \end{cases} \quad [\text{kg}^{-1}]$$

- Effective updraft speed  $w_{nuc}$  for nucleation, including turbulence, radiative cooling and parameterized convection:

$$w_{eff} = \bar{w} + 0.7 \sqrt{\frac{2TKE}{6}} - \frac{c_p}{g} \left. \frac{\partial T}{\partial t} \right|_{\text{radiation}}$$

$$w_{nuc} = \max[w_{eff}, w^*]$$

$$w^* = \left( -g z_{topcon} \frac{w' \Theta'_{v,S}}{\Theta_{v,S}} \right)^{1/3} \quad (\text{convective velocity scale after Deardorff})$$

- $z_{top\_con}$ : PBL height as determined from  $\Theta_v < \Theta_{v,surf} + 0.5 \text{ K}$ , or upper bound of lowest continuous „ $clc\_con$ “ layer

# Segal & Khain scheme in COSMO radiation

## $R_{eff}$ in SGS clouds:

- SGS water clouds with a fixed  $R_{eff}$ : Tuning parameter **reff\_ini\_c** (default: 5 $\mu$ m) **luse\_reff\_ini\_c\_as\_reffc\_sgs = .TRUE.**
- Improvement: SGS  $R_{eff}$  treated same way as in grid scale clouds - **luse\_reff\_ini\_c\_as\_reffc\_sgs = .FALSE.**

but using  $LWC_{SGS} = QC_{RAD} / (CLC * radqcfact)$

$$QC_{RAD} = QCI_{CON} * CLC_{CON} + QC_{SGS} * CLC_{SGS} * (1 - CLC_{CON})$$

$$R_e = c_1 \left( \frac{qc}{nc} \right)^{c_2}$$

# Segal & Khain scheme in COSMO microphysics

## Number concentration of cloud droplets in 1-mom scheme options:

### → **icloud\_num\_type\_gscp = 1**

- Cloud number concentration is a tuning parameter **cloud\_num**  
default:  $500 \text{ cm}^{-3}$

### → **icloud\_num\_type\_gscp = 4**

Cloud number concentration is calculated using CAMS + SK the same way as for `itype_num_type_rad = 4`

- ### → The new `cloud_num` (`qnc`) effects the 1-mom via the auto-conversion parameterization (cloud water → rain water):

$$\frac{d(qc)}{dt} \sim -\frac{qc^4}{qnc^2} = -\frac{qc^2}{xc^2} \quad (xc = \text{mean droplet mass})$$

- ### → **The effects on radiation (effective radius) and on microphysics can be separated or combined**

# CAMS prognostic aerosols

itype\_aerosol = 4

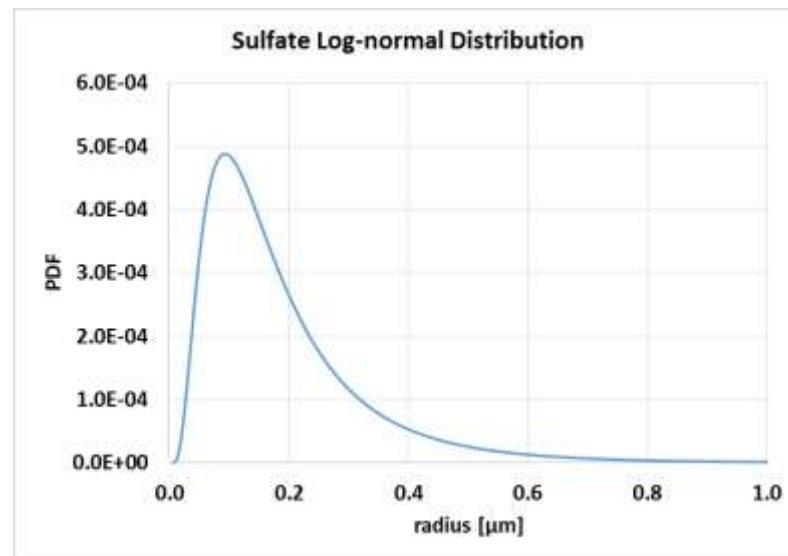

- Built on the ECMWF NWP system with additional prognostic aerosol variables
- Input aerosols analysis:
  - NASA/MODIS Terra and Aqua Aerosol Optical Depth at 550 nm
  - NASA/CALIOP CALIPSO Aerosol Backscatter
  - AATSR, PMAP, SEVIRI, VIIRS
- Verification based on AERONET  
(text adapted from Benedetti CUS2016)

- Only nucleation & accumulation modes are accounted in SK
- $r_{mode,SK} = [0.02 \mu m, 0.04 \mu m]$
- Therefore, from CAMS we take only hydrophilic organic matter, black carbon & Sulfate. Other species number concentration is neglected.
- SK was calculated for NaCl. The different chemical composition effects the hygroscopicity factor (B) in the (Kholer equation)

$$r_{Ncrit} = \frac{A}{3} \left( \frac{4}{BS^2} \right)^{1/3}$$

- $r_{crit,Kohler} \propto B^{-1/3}$ . Since  $B_{NaCl} \approx 2B_{Sul}$ ,
- $r_{crit,Sul} \approx 1.24$ ,  $r_{crit,NaCl}$  NC does not change more than **5%** for a large range of  $r_{crit}$

# Total forecast scores

2018042500

# Total forecast scores

- All averaged scores: T, RH, WS, Prof., Rain (except WD) showed better results for the new all-included scheme compared to the operational set-up
- More testing are on its way...

## Concluding remarks and outlook

- A new cloud droplets number concentration based on CAMS prognostic aerosols concentrations and Segal & Khain nucleations scheme is implemented.
- More realistic approach to define cloud droplets densities and effective radii of grid scale and sub-grid scale clouds
- High sensitivities of radiation, T2m, rain, QC etc.
- Next steps:
  1. Implementation of Khain et al. approach to effective radius + LWC
  2. 2-mom scheme
  3. Ice nucleation
  4. Mixed aerosols types
  5. Testing against observations
  6. Test version in IMS (?)

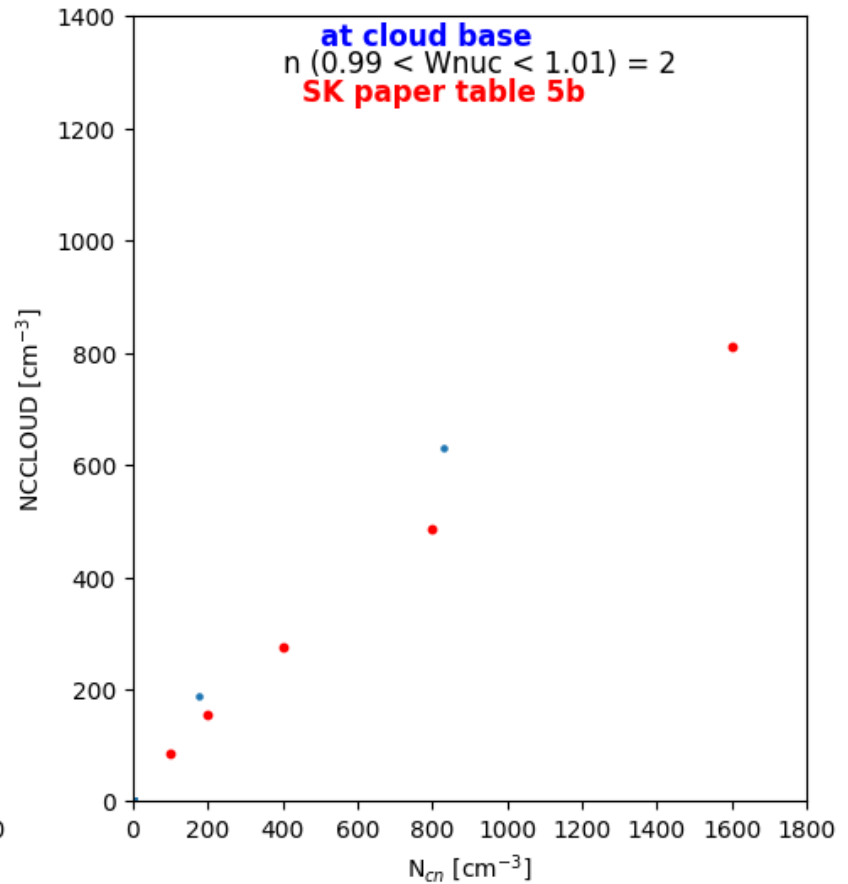

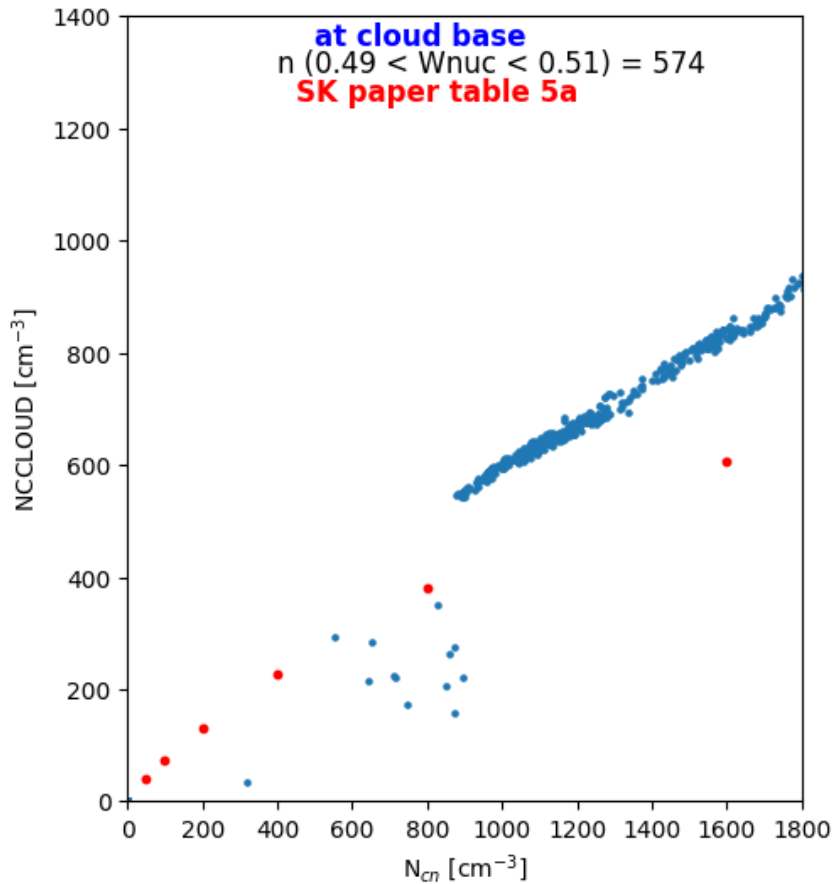

Thank You for Listening  
and Happy New Hebrew Year!
