Low clouds over-estimation

20200819 00 UTC ICON-IT run

In a grid point, where COSMO-IT has no cloudiness, the low cloud cover (CLCL) increases with the time step where no cloud water (QC) is present on model layers, but relative humidity is larger than 90%.

Conclusions

- In this summer case study ICON-IT over-estimates the low cloudiness over Italian area. Such over-estimation is not found in medium and high clouds.
- To avoid the effects of DA we use IFS analysis. In this case ICON-IT tends to form the low cloudiness (with cloud water $QC=0$) in excess during the first hour of integration where relative humidity is $> 90\%$.
- Could this bias in the low clouds could be related to the failures of ICON-IT in developing some intense deep convection events over land?
