
Some further major changes in int2lm V2.03

Ulrich Blahak
Deutscher Wetterdienst, Offenbach

→ Concerning non-hydrostatic input models (COSMO, ICON, UM, CM):

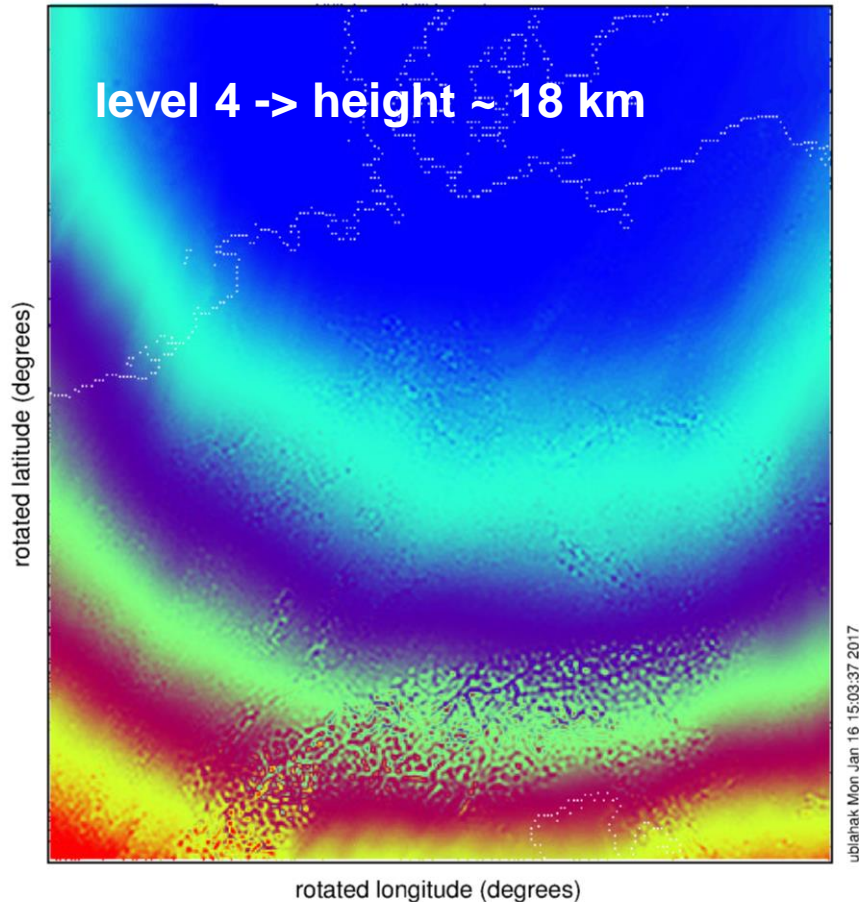

- Methods of adapting vertical profiles to new orography (deeper valleys, higher mountain tops in COSMO orography) --- **all 3D variables except pressure**
- Profiles of **W blended to „terrain following“ values** (according to U and V) near the surface
- Computation of (hydrostatically balanced) pressure: **pressure no longer interpolated but computed analytically** from interpolated profiles of T and QV – **this is a bugfix rather than a change!**

→ Concerning ICON input only:

- Bugfix:
 - Surface temperature T_{SO} (initial data) should be adapted to the new orography by way of conservation of differences to near-surface atm. T_{ke} .
 - But for ICON input, this was done wrong so that effectively T_{SO} was not adapted but only horizontally interpolated!
- Adaptation to high-resolution near-surface T_{ke} only near the soil surface. At deeper layers blending to a climatological height correction

Pressure computation

OLD deviation from reference pressure (Pa)

Range of deviation from reference pressure: 320 to 420 Pa
Range of rotated longitude: -5 to 5.5 degrees
Range of rotated latitude: -5 to 6.5 degrees
Current time: 0 seconds since 2016-04-25 00:00:00
Current level: 3
Frame 1 in File TEST_V2.03_ref_ptest_ncdf/laf2016042500.nc

NEW deviation from reference pressure (Pa)

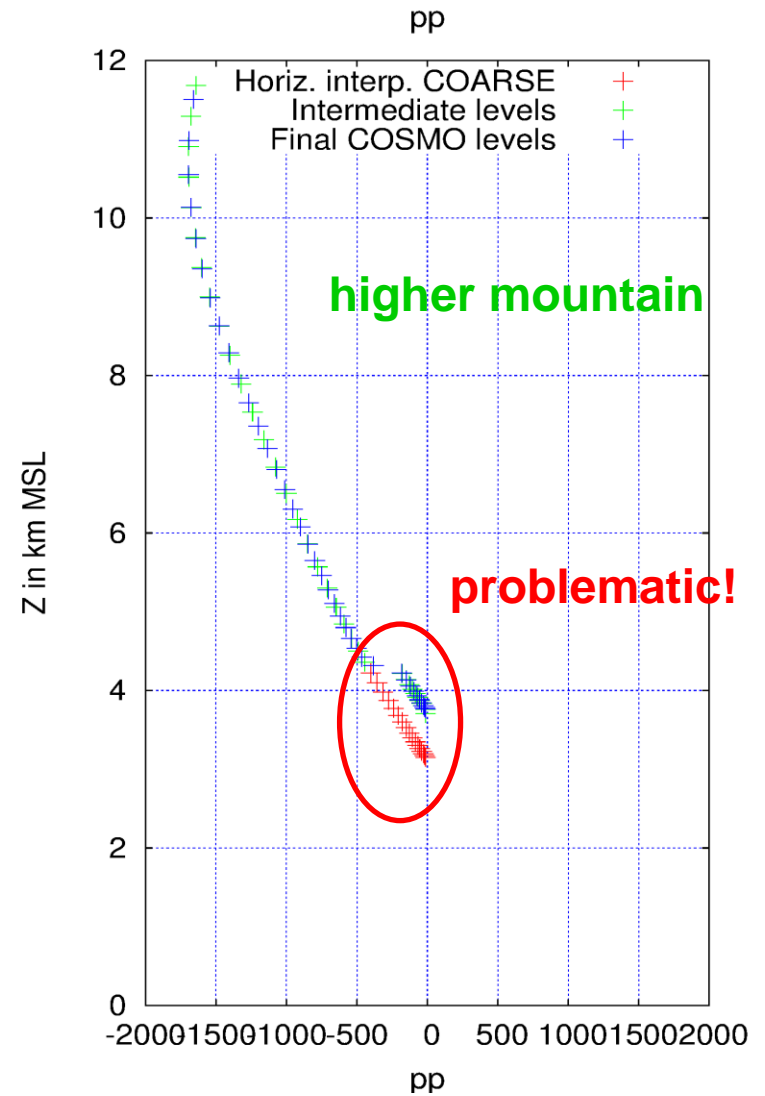

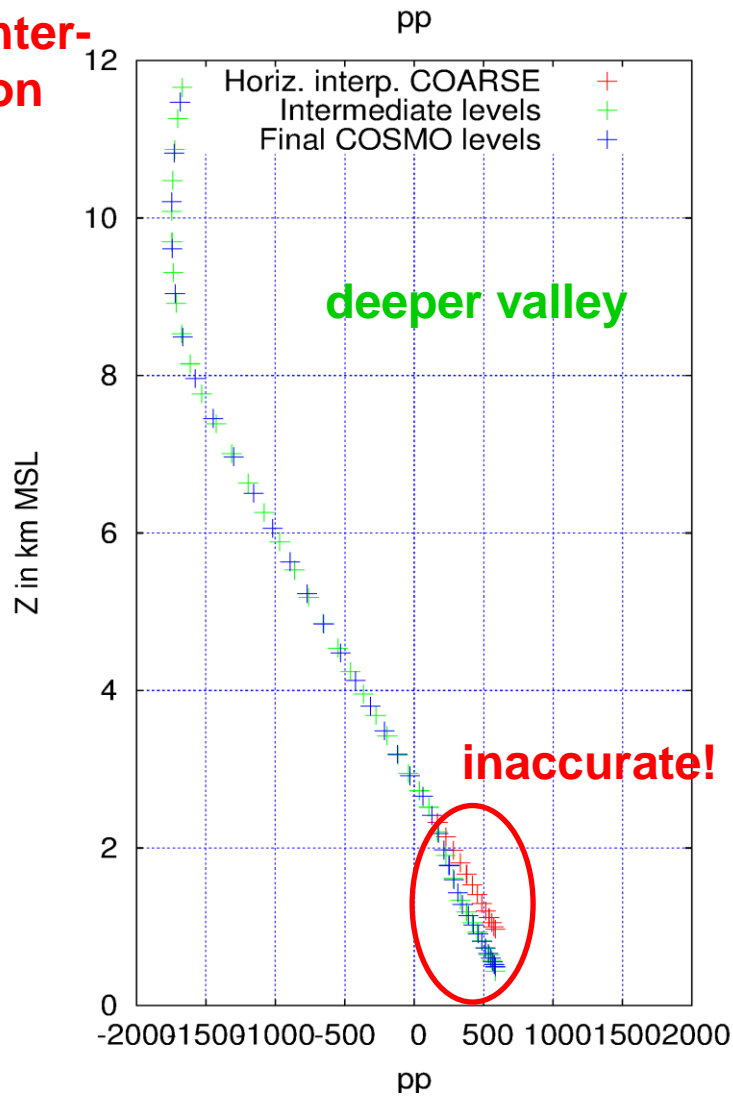

Range of deviation from reference pressure: 320 to 420 Pa
Range of rotated longitude: -5 to 5.5 degrees
Range of rotated latitude: -5 to 6.5 degrees
Current time: 0 seconds since 2016-04-25 00:00:00
Current level: 3
Frame 1 in File TEST_IEU2DE_2016042500_V2.03_test_ptest-itYPE2_simply-inte

Pressure computation

**OLD inter-
polation
of PP**

- **New: PP is no longer interpolated, but analytically computed** (integrated) from hydrostatic equation, based on the before interpolated T- and QV profiles:

$$\boxed{\frac{\partial p}{\partial z}} = -g \frac{p(z)}{R_D T(z) (1 + 0.61 q_v(z) - q_x(z))} = \boxed{-g \frac{p(z)}{R_D T_v(z)}}$$

- **New: PP is no longer interpolated, but analytically computed** (integrated) from hydrostatic equation, based on the before interpolated T- and QV profiles:

$$\boxed{\frac{\partial p}{\partial z}} = -g \frac{p(z)}{R_D T(z) (1 + 0.61 q_v(z) - q_x(z))} = \boxed{-g \frac{p(z)}{R_D T_v(z)}}$$

If $T_v(z) = T_v(z_1) - \gamma_v (z_2 - z_1)$ is assumed in layer from z_1 to z_2

$$\text{with } \gamma_v = \frac{T_v(z_1) - T_v(z_2)}{z_2 - z_1}$$

- **New: PP is no longer interpolated, but analytically computed** (integrated) from hydrostatic equation, based on the before interpolated T- and QV profiles:

$$\boxed{\frac{\partial p}{\partial z}} = -g \frac{p(z)}{R_D T(z) (1 + 0.61 q_v(z) - q_x(z))} = \boxed{-g \frac{p(z)}{R_D T_v(z)}}$$

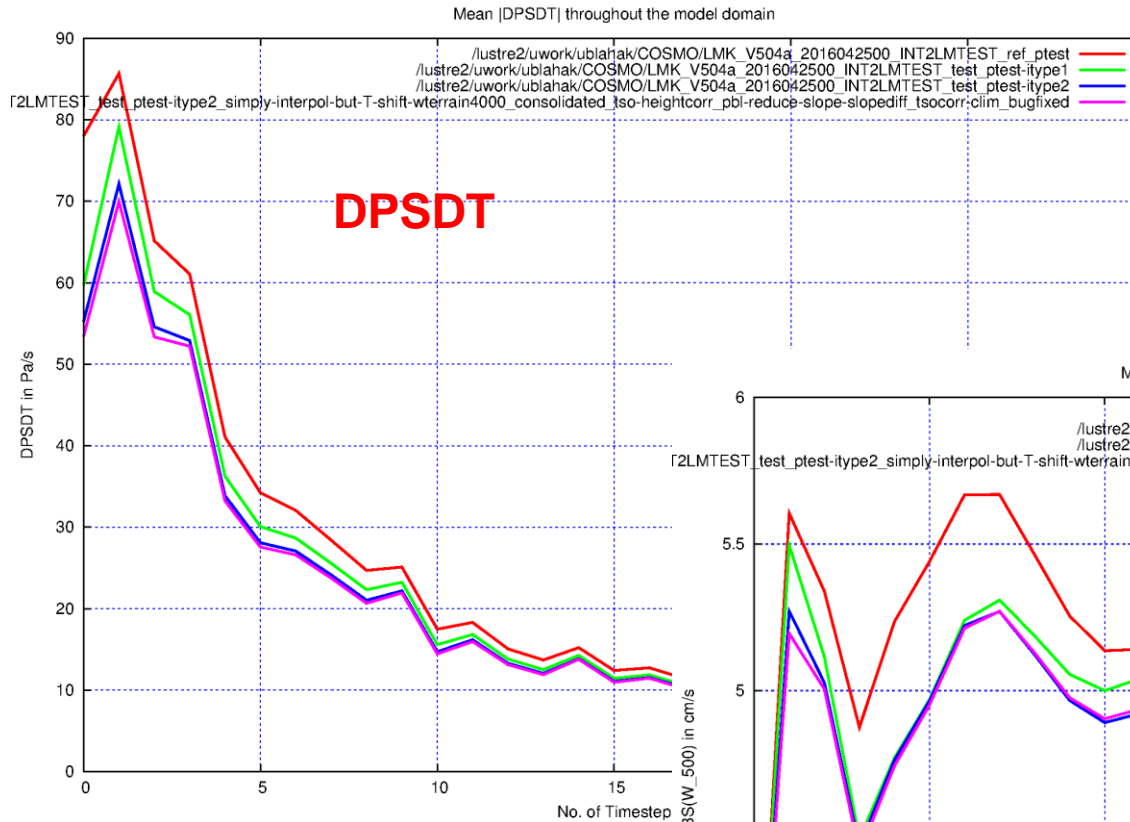

If $T_v(z) = T_v(z_1) - \gamma_v (z_2 - z_1)$ is assumed in layer from z_1 to z_2

$$\text{with } \gamma_v = \frac{T_v(z_1) - T_v(z_2)}{z_2 - z_1}$$

Then the solution of this DGL for $p(z_2)$ is

$$p(z_2) = p(z_1) \left(1 - \frac{\gamma_v}{T_v(z_1)} (z_2 - z_1) \right)^{\frac{g}{R_d \gamma_v}}$$

„Crow’s-feet“ stem from small snow amounts in ICONEU-input (partial snow cover). In this case, int2lm clips T_S to -0.8°C at, and because this is not the case in the ICON input data, the clipping is inherited to the soil levels by conservation of the vertical differences!

rotated latitude (degrees)

rotated latitude (degrees)

ublahak Tue Jan 17 14:36:01 2017

New namelist parameters (/CNTRL/)

PARAMETER	DEFAULT	TYPE	MEANING
itype_profiles_vert_interp	2	INT	1 = old method 2 = new method
itype_balance_pp	2	INT	1 = old method (for Leapfrog) 2 = new method (for RK-core)
itype_fast_waves_lm	2	INT	If itype_balance_pp = 2: 1 = „old“ RK fast waves solver 2 = „new“ RK fast waves solver (SC-form)
lmultlay_deepsoil_clim_hcorr	.TRUE.	L	Whether or not to blend the T_SO height adaption from conservation of vertical differences to the T _{ke} near the surface towards a climatological height correction (-0.007 K/m) at deeper layers.

Eliminated: lbalance_pp (because this has to be done always!)

→ Non-hydrostatic input models:

- Pressure now spatially much more smooth over mountains
 - less initial noise if COSMO starts from interpolated analysis
 - less noise at the boundaries
- New methods for vertical interpolation of the other 3D fields also lead to a reduction of the initial noise
- Blending to terrain-following W near the surface also reduces noise

→ ICON input:

- Now soil temperature T_{SO} in initial data is truly adapted to the COSMO orography and near-surface T
- Option to blend T_{SO} from pure T_{ke} –difference conservation near the surface to a pure climatological height correction at larger depth
