

Comparison of ICON-EPS and COSMO-EPS over the Eastern Mediterranean

Pavel Khain, Alon Shtivelman, Anat Baharad, Yoav Levi
Israel Meteorological Service

Overview

Which option of ensemble structure is better?

No model physics perturbation

18 methods to choose the BC

SPPT

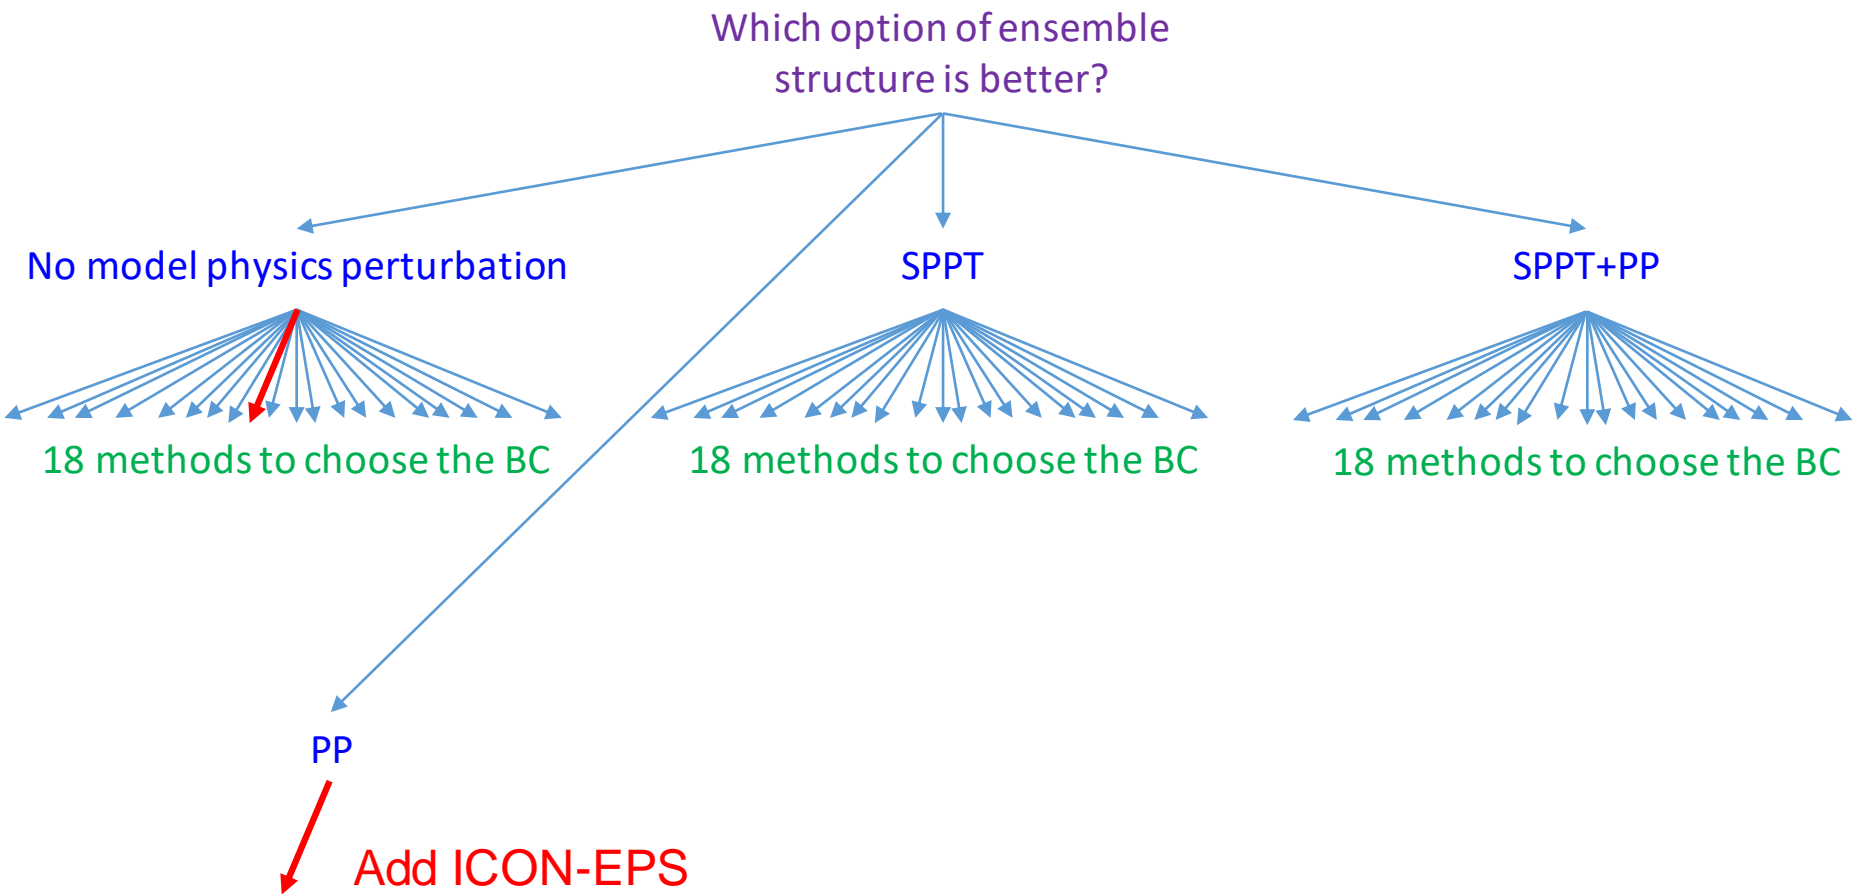

18 methods to choose the BC

SPPT+PP

Overview

Observations Representativity Error

Observations Representativity Error (ORE) versus time of the day for EC-ENS (blue) and C3-ENS (black). Panels a-c present the ORE for 2m-temperature, 2m-relative humidity and 10m-wind speed, respectively. The winter, spring, summer and autumn seasons are represented by solid, dashed, dotted and dash-dotted lines, respectively. The dashed red line represents the ORE used in Klasa et al., 2018.

Verification of near surface variables

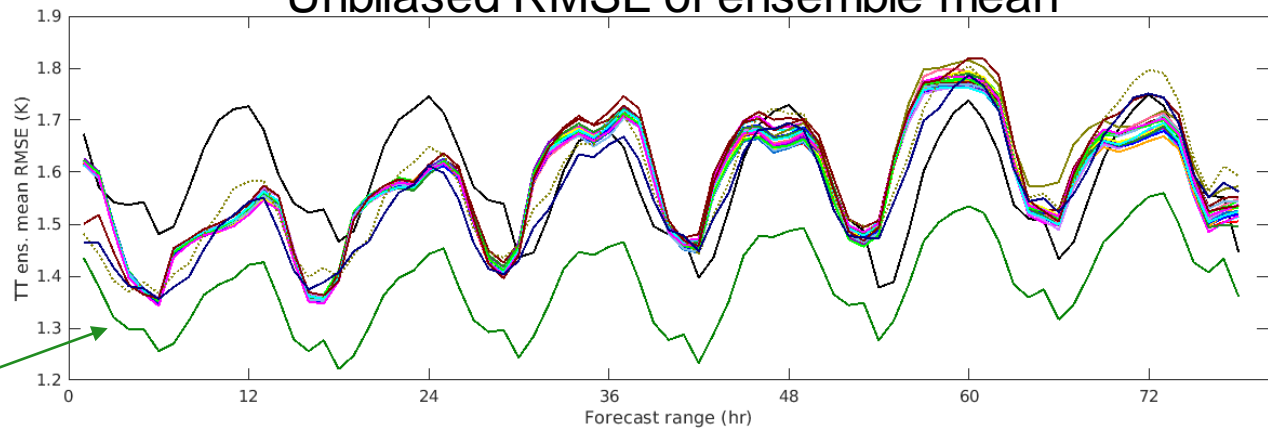

Winter: 22/12/2019-10/01/2020, 05/02/2020-16/02/2020 – 61 runs

Summer: 27/08/2020-07/09/2020 – 24 runs

- We use unbiased RMSE and a spread boosted by observations representativity error
(Bouttier et al., 2012; Klasa et al., 2018; Westerhuis et al., 2016, Ben Bouallegue, 2020)
- The verification was performed against 81 automatic weather stations

Winter 2020: 2m Temperature
 COSMO: No physical perturbations
 ICON: No physical perturbations

Verification of precipitation

ICON-EPS vs. COSMO-EPS

- 61 winter runs verified against the Radar composite (QPE).
- 6 hourly precipitation, forecast ranges 12-78h. Averaged over not up-scaled thresholds of 0.5, 1, 2 and 5 mm/6h, and up-scaled thresholds of 10 and 20 mm/6h.
- The error bars were obtained using boot strap method.

Summary

1. For COSMO-EPS we use random EC-ENS members for BC, together with SPPT perturbations
2. Near surface fields: ICON-EPS are **better** than COSMO-EPS in RMSE of ensemble mean (skill), but **worse** in spread-skill ratio!
3. Precipitation: ICON-EPS is **a bit worse** than COSMO-EPS in precipitation scores
4. Conclusion: **Waiting for SPPT in ICON** 😊
